

Immunization De-duplication: A Program Developed in New York City to Reduce Duplicate Immunizations

Alex Ternier, MPH

Vikki Papadouka, PHD, MPH

Citywide Immunization Registry

**New York City Department of Health and Mental
Hygiene**

American Immunization Registry Association

IIS Meeting 2012

September 19-20 | Saint Paul, MN

Objectives

- Background - Citywide Immunization Registry (CIR)
- Describe the design of CIR's immunization de-duplication program
- Discuss implementation details
- Discuss impact on CIR data quality
- Share plans for improving the program

Citywide Immunization Registry

- NYC's CIR was implemented in 1997
 - NYC population: 8.2 million
 - Approximately 2 million (24%) are under age 19
 - Annual birth cohort is 125,000
 - Reporting of immunization for individuals 0-18 years of age is required by a mandate
 - > 500,000 immunizations received each month
 - ~1,850 NYC providers - 93% participate in CIR
 - Database has 4.7 million records and 58 million immunizations

Immunization Duplication in an IIS

- Duplicate immunizations:
 - Two or more immunizations within the same vaccine group that represent a single vaccination event
 - DTaP on 2/4/2010 and 2/5/2010
 - Hib/HepB and HepB both on 4/6/2005
 - May be from the same source or different sources
- Level of immunization duplication in an IIS is difficult to assess

Why are Duplicate Immunizations a Problem?

- Duplicate immunizations:
 - Complicate forecasting programs and data exchange
 - System must choose between 2 or more shots in a series
 - Render vaccination histories confusing
 - Undermine the credibility of IIS data

Before the De-duplication Project

- In 2010, CIR
 - Contained about 5-7% duplicate immunizations
 - Received an average of 3,700 requests per month from providers for manual immunization corrections (a provider cannot modify shots submitted by another provider)

The De-duplication Model

Three General rules:

1. Combination shots are deleted only when in comparison with the same formulation (different dates)
2. Only a single pair can be evaluated from a cluster
3. There is always a surviving shot

The De-duplication Model (2)

- Designed in 3 stages:
 - Stage 1: Identify clusters of duplicate immunizations
 - Stage 2: Perform pair-wise comparison based on a decision matrix that scores each immunization
 - Stage 3: Delete the lowest scoring immunization

Stage 1: Identification of Duplicate Clusters

- Duplicate cluster are:
 - Two or more immunizations
 - from the same vaccine group
 - administered within 0, 1, or 2 days
 - One valid plus 1 or more invalid shots

Hib Cluster

DTaP/IPV/Hib	3/3/2010
Hib-PRP-T	3/3/2010
Hib NOS	3/5/2010

Polio Cluster

IPV	11/1/2005
Polio NOS	11/1/2005

Stage 2: Pair-wise Comparison

Assign a score to each vaccine based on the weight of each data element associated with the vaccine

Data elements	Weight
Combo	100
Manufacturer or lot number	3
More specific	2
Entered/modified by CIR	2
VFC eligibility - not UNK	1
By vaccinator	1
Before license date or after end date	-5

Vaccine Specificity

- Vaccine specificity - hierarchy from most to least specific

1. RotaTeq	code 116	3. Rotashield	code 74
2. Rotarix	code 119	4. Rota NOS	code 122

- Patient age is also used to determine the appropriateness of a vaccine in the following groups:
DTP, HepA, Meningococcal

If age is < 7 years

1. DTaP5antig
2. DT
3. DTaP
4. DTaP NOS
4. DTP
6. Tdap
7. Tdpreserfree
8. Td

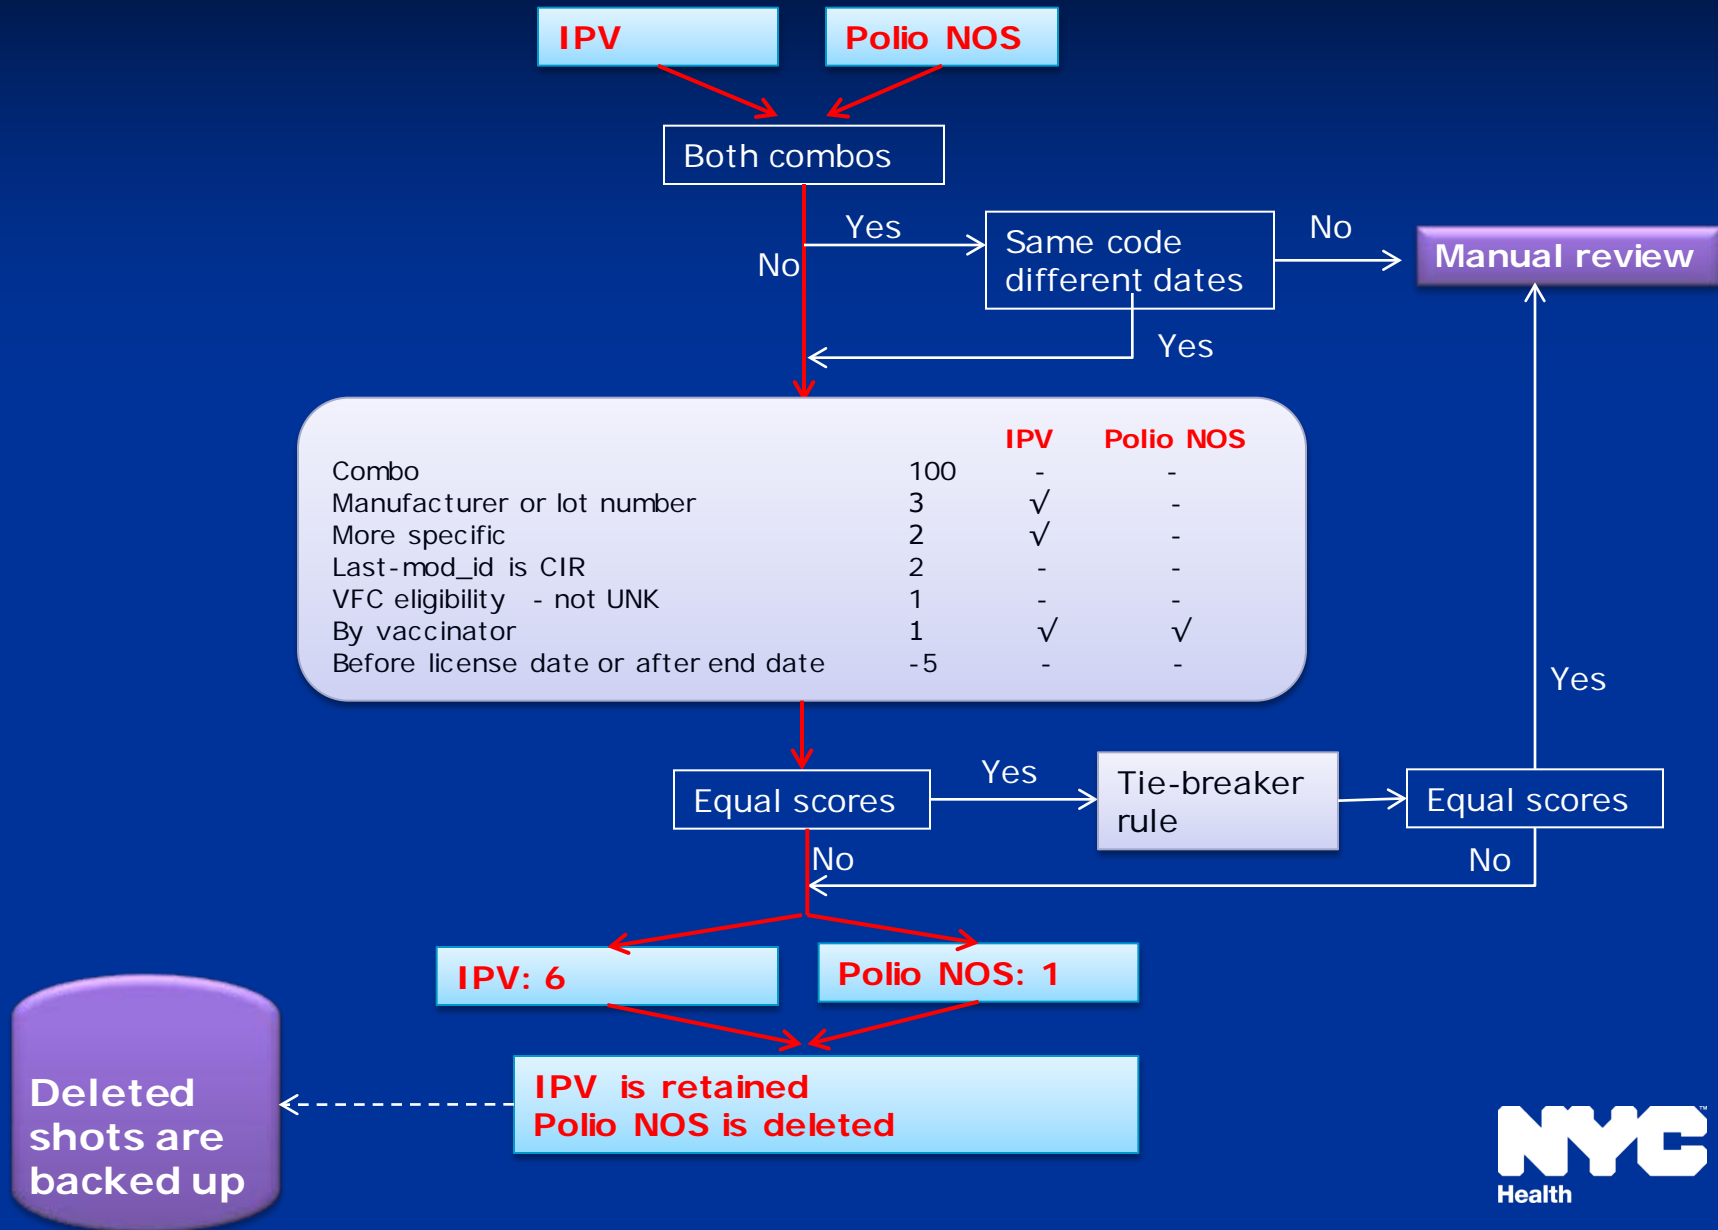

If age is => 7 years

1. Tdap
2. TdpreserFree
3. Td
4. DtaP5antig
5. DT
6. DTaP
7. DTaP NOS
8. DTP

Stage 3: Resolution

- Select the “best” vaccine
- Delete lowest-scoring vaccine
- Apply tie-breaker logic if scores are tied (using entry date time)
- Send to manual review if still tied after the tie-breaker

Decision Matrix

Required Database Changes

- New fields/tables added to support the deduplication process:
 - To store the most recent deduplication date for each record
 - To store data on each patient processed by the program
 - To store back-up data on each deleted immunization
 - To store statistics for each run of the program

Results

- First runs on the entire database (in 2010):
~ 1.5 million deletions
- Weekly runs thereafter – only on new records and records that were modified since the last run: 10 to 12,000 deletions
- As of August 2012: a total of 2.9 million immunizations deleted (~70% of all duplicates)
 - 725,000 patient records affected, or 16% of CIR

Profile of Duplicates

Most Frequent Duplicates

Most frequent manual review pair are 2 combos or 2 vaccines with same code, different dates

Results (continued)

Additional measure

- Provider requests for manual corrections and deletions decreased by over 50% - from 3,700 to ~1,700 per month

MANUAL_IMM_UPDATES

Conclusions

- Immunization deduplication is feasible within a large IIS
- Fairly simple methodology – large impact
- Manual review is not feasible for a large IIS like the CIR
- Program has a significant impact on CIR data quality and operations

Considerations

- De-duplication program must be set up as a routine activity for highest return on investment
- Interval chosen is proportionally related to level of manual review possible (staffing), potential errors

Next Steps

- Further evaluate impact of the program on specific types of immunization, and proportion that is sent to manual review
- Consider expanding the 'duplicate definition window' from 3 days to a wider range
